

Adult lower-grade glioma cohort (n = 155)
77 malignant-transformation events · 6 non-MT deaths · 72 censored

CONCORDANCE
CE hazard ratio is order-of-magnitude consistent across four independent frameworks;
the IDH-mutant subgroup amplifies the CE effect (Bayesian HR 92.2)

CONCLUSIONS
Contrast enhancement is the dominant baseline predictor · GTR confers an approximately two-thirds (~68%) hazard reduction
no single radiomic feature is credible under horseshoe · two-feature signature detectable only in midpoint Fine-Gray

Sensitivity analyses: par_ratio grid · adult-only cohort · era split at 2010 → all conclusions unchanged
